AAT50138-T50359 represent target sequences for the rabbit cholesterol ceter transfer protein (CETP) hammerhead (HH) ribozymes (see AAT50160-CCT 50546). CETP is a 74 kD glycoprotein that facilitates neutral lipid transfer between plasma lipoproteins. The numbering of the targets refers to the position of the cleavage site in full length CETP. The ribozyme are able to cleave mRNA from the gene encoding CETP, thereby blocking cynthesis and/or expression of the mRNA. By inhibiting CETP, the reverse cholesterol transport (RCT) pathway can be inhibited (or eliminated) thereby preventing the reduction in size density of the high density of lipoproteins (HDL), prolonging HDL half life, and therefore increasing HDL levels. The ribozymes can be used to treat conditions associated with abnormal levels of CETP, specifically atherosclerosis, familial computations of diabetes, transplant, atherosclerosis, familial complications of diabetes, transplant, atheroctions and angioplastic restenosis. By inhibiting CETP, the levels of HDL and low density createnosis. By inhibiting CETP, the levels of HDL and now density createnosis. By inhibiting CETP, the levels of HDL and now density createnosis. By inhibiting CETP, the levels of HDL and low density createnosis in LDL), and the HDL:LDL ratio are favourably altered (a mutations in diseased cells, and to detect CETP mRNA. As the HH ribozymes can also be used diagnostically to study genetic drift and carrier appears the CETP man and they have low non-specific
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Hammerhead ribozyme; cholesterol ester transfer protein; mRNA cleavage; neutral lipid transfer; plasma lipoprotein; atherosclerosis; atheroectomy; everse cholesterol transport; high density lipoprotein; therapy; CBTP; familial hypercholesterolaemia; dyslipidaemia; hypoalphalipoproteinaemia; peripheral vascular disease; hyperbetalipoproteinaemia; RCT; inhibitor;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                New ribozyme(s) for cleaving cholesterol ester transfer protein mRNA -
useful for preventing or treating initial development, progression or
regression of vascular diseases, esp. familial hypercholesterolaemia.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     ö

```
AAT50138-T50359 represent target sequences for the rabbit cholesterol ester transfer protein (CETP) hammerhead (HH) ribozymes (see AAT50360-T50566. CETP is a 74 kD 91ycoprotein that facilitates neutral lipid transfer between plasma lipoproteins. The numbering of the targets refers to the position of the cleavage site in full length CETP. The ribozyme are able to cleave mRNA from the gene encoding CETP, thereby blocking synthesis and/or expression of the mRNA. By inhibiting CETP, the reverse choisesterol transport (RCT) pathway can be inhibited (or eliminated) thereby preventing the reduction in size density of the high density lipoproteins (HDL), prolonging HDL half life, and therefore increasing HDL levels. The ribozymes can be used to treat conditions associated with abnormal levels of CETP, specifically atherosclerosis, samilial hypercholesterolaemia, peripheral vascular disease, dyslipidaemia, hyperbetalipoproteinaemia, hypoalphalipoproteinaemia, vascular complications of diabetes, transplant, atherectomy and angioplastic restenosis. By inhibiting CETP, the levels of EMDL and low density and into low of the levels 
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              decrease in LDL levels, and a corresponding increase in HDL levels). The HTibozymes can also be used diagnostically to study genetic drift and mutations in diseased cells, and to detect CETP mRNA. As the HH ribozymes target specific regions of the CETP gene, they have low non-specific

ANA ANA 9608-T49863 represent target sequences for the human cholesterol cster transfer protein (CETP) hammerhead (HH) ribozymes (see AAT49881-15017). CETP is a 74 KD Glycoprotein that facilitates neutral lipid to the bosition of the cleavage site in full length CETP. The ribozyme ct to the position of the cleavage site in full length CETP. The ribozyme ct binds to 5 nucleotides either side of this site, provided the sequence UH is immediately upstream. The ribozymes are able to cleave MRNA from the cis immediately upstream. The ribozymes are able to cleave MRNA from the companient of the ribozymes are cleaved or expression of the came encoding CETP, thereby blocking synthesis and/or expression of the came inhibited (or eliminated) thereby preventing the reduction in size density of the high density lipoproteins (HDL), prolonging HDL half life, and therefore increasing HDL levels. The ribozymes and be used to treat conditions associated with abnormal levels of CETP, specifically familial hypercholesterolosterolementa, atherosclenosis, peripheral vascular disease, hypercholesterolosis. By inhibiting CETP, the levels of HDL and Low conditions complications of diabetes, transplant, atheredown and corresponding increase in LDL levels, and a corresponding increase in HDL levels. The HH ribozymes can also be used diagnostically to study genetic drift cathorymes target specific regions of the CETP gene, they have low non-confict activity

Human CETP HH ribozyme target sequence #550.

(first entry)

28-FEB-1997

AAT49643;

```
Caster transfer protein (GETP) hammerhead (HH) ribozymes (see AAT50360-
CET50546). GETP is a 74 kD glycoprotein that facilitates neutral lipid of transfer between plasma lipoproteins. The numbering of the targets refers to the position of the cleavage site in full length CETP. The ribozyme are able to cleave mRNA from the gene encoding CETP. The ribozymes are able to cleave mRNA from the gene encoding CETP, thereby blocking synthesis and/or expression of the mRNA. By inhibiting CETP, the reverse cholesterol transport (RCT) pathway can be inhibiting CETP, the reverse thereby preventing the reduction in size density of the high density inpoproteins (HDL), prolonging HDL half life, and therefore increasing HDL levels. The ribozymes can be used to treat conditions associated with abnormal levels of CETP, specifically atheroscierosis, familial hypertholesterolaemia, peripheral vascular disease, dyslipidaemia, hyperipheral vascular disease, dyslipidaemia, hyperipheral vascular disease, dyslipidaemia, complications of diabetes, transplant, atheretocumy and angiophastic restenosis. By inhibiting CETP, the levels of HDL and low density complications of labetes, transplant, atheretocumy and angiophastic crestenosis. Lobi. levels, and a corresponding increase in LDL levels, and a corresponding increase in LDL levels of HT ribozymes can also be used diagnostically to study genetic drift and mutations in diseased cells, and to detect CETP mRNA. As the HH ribozymes can also be used diagnostically to study genetic drift and mutations in diseased cells, and to detect CETP mRNA. As the HH ribozymes can also be used diagnostically to study genetic drift and content and corresponding the drift and content and content of the HT ribozymes the HT ribozymes can also be used diagnostically as the HH ribozymes can also be used diagnostically as the HH ribozymes the HT ribozymes the HT ribozymes as the content of the HT ribozymes as the

AATS0138-T50359 represent target sequences for the rabbit cholesterol cster transfer protein (CETP) hammerhead (HH) ribozymes (see AAT50360-510546). CETP is a 74 kD glycoprotein that facilitates neutral lipid transfer between plasma lipoproteins. The numbering of the targets refers to the position of the cleavage sithe in full length CETP. The ribozyme are then binds to 5 nucleotides either side of this site. The ribozymes are able to cleave mRNA from the gene encoding CETP, thereby blocking synthesis and/or expression of the mRNA. By inhibiting CETP, the reverse consistent (RCT) pathway can be inhibited (or eliminated) therefore increasing the reduction in size density of the high density conclusions (HDL), prolonging HDL half life, and therefore increasing HDL levels. The ribozymes can be used to treat conditions associated with the levels of CETP, specifically atherosclerosis, familial computations of diabetes, transplant, atherosclerosis, familial computations of diabetes, transplant, atherosclerosis, familial computations of diabetes, transplant, atherecomy and angioplastic restenosis. By inhibiting CETP, the levels of HDL and low density decreased in LDL), and the HDL:LDL ratio are favourably altered (a decrease in LDL) levels, and a corresponding increase in HDL levels. CH H ribozymes can also be used diagnostically to study genetic drift and mutations in diseased cells, and to detect CETP mRNA. As the HH ribozymes can greated see they have low non-specific neutral lipid transfer; plasma lipoprotein, atherosclerosis; atherectomy, reverse cholesterol transport; high density lipoprotein; therapy, CETP; familial hypercholesterolaemia, dyslipidaemia; hypoplahalipoproteinaemia; peripheral vascular disease; hyperbetalipoproteinaemia; RCT, inhibitor; angloplastic restenosis; low density lipoprotein; diabetes; HDL; rabbit; cholesterol ester transfer protein; mRNA cleavage; New ribozyme(s) for cleaving cholesterol ester transfer protein mRNA useful for preventing or treating initial development, progression or regression of vascular diseases, esp. familial hypercholesterolaemia. The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-
2'deoxyuridine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primars for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       The present sequence is a 5-methyl-2'-deoxycytidine/5-(3-methyl-1-butynyl)uracil modified triplex forming oligonuclectide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)

                                                                                                                                                                                                                                                                                                                                                                                                                                                             The present sequence is a 5-(1-propynyl)-2'-deoxycytidine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of sytosine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                         Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Gaps

The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Modification, triplex, duplex, nucleomonomer analogue, unsaturated group;

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           The present sequence is a 5-(1-propynyl)-2'-deoxycytidine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of cytosine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          The present sequence is a 5-methyl-2'-deoxycytidine/5-(2-thienyl)-2'deoxyuridine modified triplex forming oligonucleotide, comprising nucleomnomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     ò
                                                                                                                                                                                                                                                                                           The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-
2'deoxyuridine modified triplex forming oligomuclectide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substitute provides enhanced binding capacity in the pyrimidine duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)

The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-2'deoxyuridine modified triplex forming oligonaclectide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The S-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhance nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapoutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Gabs

The present sequence is a S-methyl-2'-deoxycytidine/5-(1-propynyl)-
2'deoxyuridine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The S-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  The present sequence is a 5-methyl-2'-deoxycytidine/5-(2-pyridinyl)-2'deoxyuridine modified triplex forming oligonucleotide, comprising nucleomenomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding dapacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological ph conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         o,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.

The 5-dubstituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Modification, triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.
                                                                                                                                                                                                                                                                                                                Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.

The present sequence is a 5-(2-pryridinyl)-2'-deoxycytidine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of suptraine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.

The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-2'deoxyuridine modified triplex forming oligonucleotide, comprising uncleomoner analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substitute provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PP field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.
                                                                                                                                                                                                           Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      ö

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 ö
                                                                                                                                                                                                                                                                                                                                                                            The present sequence is a 5-(1-propynyl)-2'-deoxycytidine/5-(1-propynyl)-2'-deoxycytidine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of cytosine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological ph conditions. The lipophilic groups can also enhance cell permeation and upteake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal coligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Modification, triplex, duplex, nucleomonomer analogue, unsaturated group, pyrimidine ring, inhibition, gene expression, antisense, therapy, research, diagnosis, probe, primer, ss.

The present sequence is a 5-methyl-2'-deoxycytidine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of cytosine containing an unsaturated group in the pyrimidian ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.
                                                                                                                                                                                                          Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         are 5-methyl-2'-deoxycytidine all U are
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Pyrimidine ring modified triplex forming oligonucleotide ON-26.

The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-2'deoxyuridine modified triplex forming oligonuclectide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated sproup in the pyrimidine ring. The s-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapoutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.

                                                                                                                                                                                                                                                                                                                                                                                                          .
                                                                                                                                                                       The present sequence is a 5-methyl-2'-deoxycytidine/5-(3-methyl-1-butpyl) luxacil modified triplex forming oligonocleotide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance call permetation and uptake. The oligomer, which also shows enhanced normal oligomer, to inhibit gene expression, e.g. by its antisense normal oligomer, to inhibit gene expression, e.g. by its antisense providing probes or primers for research purposes, and for diagnosis by 2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Modification, triplex, duplex, nucleomonomer analogue; unsaturated group, pyrimidine ring; inhibition, gene expression, antisense, therapy, research; diagnosis; probe; primer; ss.
                                                                                                Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     /*tag= a

                                                                                                                                                                                                                The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-2'deoxycuridine modified triplex forming oligonucleotide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding double formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0 i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permetation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.

```

```
The present sequence is a 5-methyl-2'-deoxycytidine/5-methyl-2'-0-
allyluridine modified triplex forming oligonucleotide, comprising
uncleodnomer analogues of cytosine and uridine containing an unsaturated
group in the pyrimidine ring. The 5-substituted provides enhanced binding
capacity in the formation of duplexes and triplexes with single and
double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e.
under physiological pH conditions. The lipophilic groups can also enhance
cell permeation and uptake. The oligomer, which also shows enhanced
nuclease resistance, can be used to form duplexes and triplexes as a
normal oligomer, to inhibit gene expression, e.g. by its antisense
configuration, for therapeutic or research purposes, and for diagnosis by
providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-
2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Modification; triplex; duplex; nucleomonomer analogue; unsaturated group; pyrimidine ring; inhibition; gene expression; antisense; therapy; research; diagnosis; probe; primer; ss.
                                                                               Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              /*tag= a

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     ó
                                                                                                                                                                                             The present sequence is a 5-methyl-2'-deoxycytidine/5-(2-thiemyl)-2'deoxyuridine modified triplex forming oligonucleotide, comprising nucleomnomer analogues of cytosine and utidine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antiense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Modification, triplex, duplex, nucleomonomer analogue, unsaturated group, pyrimidine ring, inhibition, gene expression; antisense, therapy; research, diagnosis, probe, primer; ss.

                                                                                                                                      The present sequence is a 5-methyl-2'-O-allyldeoxycytidine modified cytoplac forming oligonucleotide, comprising nucleomonomer analogues of cytosine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological physiologicals. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   5
                 Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      "*tag=" a

                                                                                                                                                                                                                The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-2'deoxycytidine modified triplex forming oligonuclectide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and choule stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a nqrmal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Modification, triplex, duplex, nucleomonomer analogue, unsaturated group, pyrimidine ring, inhibition, gene expression, antisense, therapy, research, diagnosis, probe, primer, ss.

The present sequence is a 5-methyl-2'-deoxycytidine/5-(2-pyridinyl)-2'deoxyuridine modified triplex forming oligonuclectide, comprising nucleomonomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the primidine of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. under physiological pH conditions. The lipophilic groups can also enhance cell permeation and uptake. The oligomer, which also shows enhanced nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapeutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.) Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay. Sequence 15 BP; 0 A; 5 C; 0 G; 5 T; 5 U; 0 Other; Example 16; Col 105-106; 104pp; English.

Nucleo:monomers containing unsaturated pyrimidine base analogues - form oligomer duplexes or triplexes with nucleic acid under physiological conditions, and used in gene expression inhibition, diagnosis and assay.

Example 18; Col 125-126; 104pp; English.

The present sequence is a 5-methyl-2'-deoxycytidine/5-(1-propynyl)-2'-0-allyldeoxyuridine modified triplex forming oligonucleotide, comprising mucleomnomer analogues of cytosine and uridine containing an unsaturated group in the pyrimidine ring. The 5-substituent provides enhanced binding capacity in the formation of duplexes and triplexes with single and double stranded RNA and DNA. Triplexes can be formed at pH 7.0, i.e. can be stranded RNA and DNA. Triplexes can be formed at pB 3.0, i.e. call permeation and uptake. The oligomer, which also shows enhance nuclease resistance, can be used to form duplexes and triplexes as a normal oligomer, to inhibit gene expression, e.g. by its antisense configuration, for therapoutic or research purposes, and for diagnosis by providing probes or primers for specific RNA or DNA. (Updated on 25-MAR-2003 to correct PF field.)

single-stranded DNA fragment having a specific nucleic acid sequence in a sample. The method comprises stringently hybridizing a carrier-bonded DNA probe that comprises a single-stranded DNA probe having a carrier-bonded DNA probe that comprises a single-stranded DNA probe having a nucleic acid sequence complementary to the specific nucleic acid sequence of the single-stranded DNA fragment to be detected or quantitatively determined in the sample and a carrier comprising a substance with a very low absorbance for DNA, as bonded together via or without a spacer between them, with DNA fragments in the sample. followed by detecting or carrier-bonded DNA probe. Probes from the present invention are used for detecting point mutations associated with diseases such as cancer. The method is simple and allows very early quantitative diagnoses. The present sequence represents a DNA chain having a K-ras mutant sequence, used in an example from the present invention

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         single-stranded DNA fragment having a specific nucleic acid sequence in a single-stranded DNA fragment having a specific nucleic acid sequence in a sample. The method comprises stringently hybridizing a carrier-bonded DNA probe that comprises a single-stranded DNA probe having a nucleic acid sequence complementary to the specific nucleic acid sequence of the single-stranded DNA fragment to be detected or quantitatively determined in the sample and a carrier comprising a substance with a very low absorbance for DNA, as bonded together via or without a spacer between them, with DNA fragments in the sample, followed by detecting or them, with DNA fragments in the sample, followed by detecting or quantitatively determining the DNA fragment as hybridised with the carrier-bonded DNA probe. Probes from the present invention are used for detecting point mutations associated with diseases such as cancer. The method is simple and allows very early quantitative diagnoses. The present sequence represents a DNA chain having a K-ras mutant sequence, used in an example from the present invention
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           ö
                                                                                                                                                                                                                                                     Detection; determination; quantitation; carrier bonded DNA probe;

Probes for target muchaic actu sequences - using a detectable probe and probes for suppressing the binding to a non-target sequence which may be probes for suppressing the binding to a non-target sequence which may be the invention provides a method for suppressing the binding of a carget sequence (TS). The method involves (a) contacting the sample for a target sequence (TS). The method involves (a) contacting the sample with a set containing two or more probes under conditions suitable for the probes wild-type probe labelled with a detectable moiety and having a sequence complementary to the TS, and at least one of the other probes is a detectable wild-type probe labelled with a detectable moiety and having a sequence complementary to a non-TS which may be resent in the sample. The method also specifies that atleast one of the probe and the unlabelled probe should be a peptide mucleic acid (PNA) probe. (b) The next stop involves detecting the presence or amount of TS present in the sample by directly or indirectly quantitating the categories by a single base (the wild-type probe which hybridised to the TS. In the example given, two DNA target oligonucleotides which differed in the example given, two DNA target oligonucleotides which differed in the example given, two DNA target oligonucleotides which differed in the example given, two DNA target oligonucleotides which drawnant to DNA (AAV33234)) were detected in experimental assays using labelled PNA (V33222) which were complementary to one of the two target sequences. (see AAV33226 and AAV33242). The results showed the sample the adjust of a labelled probe directly the assay theresty improves such as the present sequence, (see AAV33236 and AAV33242). The results showed target DNA by using the horspecific binding of a labelled probe directly in mprovements in reliability since the incidence of false maganity would also be reduced. Using that several loss of improvement can be achieved in point to staimed that several loss of improvement can be achieved in poin

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       The invention provides a method for suppressing the binding of a detectable probe to a non-target sequence in an assay of a sample for a target sequence (TS). The method involves (a) contacting the sample with a set containing two or more probes under conditions suitable for the
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Assays for target nucleic acid sequences - using a detectable probe and probes for suppressing the binding to a non-target sequence which may be present in a sample.
                                                                                                                                                                                                                                                                                                                                                                                                       /*tag= a attached the Sypedite PNA linker)2-lys- group attached at the 5' end when used as a wild-type PNA attached probe; fluorescein- Fluorodite (RTM) labelling phosphoramidite- group attached at 5' end when used as wild-type DNA labelled probe; if left unmodified the probe is used as a wild-type PNA blocker probe or as a wild-type DNA blocker probe.
                                                                                                                                                                                                                                                                                     Probe; hybridisation; target sequence; TS; peptide nucleic acid; PNA; nonspecific binding; signal to noise ratio; assay; point mutation discrimination; ss.

cc probes to hybridise to nucleic acid, where, at least one of the probes is a detectable wild-type probe labelled with a detectable moiety and having a sequence complementary to the TS, and at least one of the criber probes (also known as a blocker probe) is an unlabelled or independently which may be present in the sample. The method also specifies that atleast one of the labelled probe and the unlabelled probe should be a peptide nucleic acid (PNA) probe. (b) The next step involves detecting the presence or amount of TS present in the sample by directly or indirectly quantitating the certable moiety of the detectable probe which hybridised to the TS. In the example given, two DNA target oligonucleotides which differed in the example given, two DNA target oligonucleotides which differed in the example given, two DNA target oligonucleotides which alternate the TS. In the example given, two DNA target oligonucleotides which alternate the TS. In the example given, two DNA target oligonucleotides which the mutant to DNA (AAV33234) which were detected in experimental assays using labelled PNA and DNA probes, such as the present sequence, (see AAV33235 and AAV3324).

CC Sequence by a single base (the wild-type DNA (AAV33233) and the mutant of the addition of unlabelled blocker probes, such as the present sequence, (see AAV33236 and AAV3324).

CC Septements were performed to examine, compare and quantitate the effects associated with the addition of unlabelled blocker probes, such as the correct DNA by using the blocker probes. The invention claims the teaction improves the sensitivity of the assay thereby improving the signal to improve the sensitivity of the assay thereby improving the signal to improve the sensitivity of the assay thereby improving the signal to create the incidence of false positives and false negative would also be reduced. Using this method, it is claimed that several logs of improvement can be achieved in point of mutation discrimination. (Updated on 25-MAR-2003 to ocrrect PI field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Pyrimidinone derivative; labeled binding partner; diagnostic assay; antisense; transfection complex; primer; probe; ss.

The specification describes pyrimidinone derivatives. These derivatives are used as labeled binding partners, particularly as labels for diagnostic, analytical and therapeutic applications. The derivatives used as detectable labels for diagnostic assays, to enhance diagnostic assays that use oligonucleotides and to improve potency of also assays that use oligonucleotides and to improve potency of altering intracellular metabolism of complementary RNA sequences encoding at arget gene. They are also used in transfection complexes to deliver oligonucleotides into cell cyroplasm and in PCR e.g. as primers, and ligase chain reaction (LCR) e.g. as probes. The derivatives have increased affinity and specificity for their complementary sequences and facilitate PCR and LCR processes. The present sequence represents a target for pyrimidinone derivatives of the invention
                                                                                                                                                                                                                                                                                                                                                                                                              ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 AAX30947-31815 represent tag sequences of transcripts that are differentially expressed in colorectal cancer, in pancreatic cancer, or in both. The tag sequences can be used to identify genes by matching the tag to a gen data base member, or by using the tag sequences as probes to isolate unidentified genes from cDNA libraries. The tag sequences can also be used in a method for diagnosing colon or pancreatic cancer in a sample suspected of being neoplastic. The method comprises comparing the level of at least one transcript in a first sample of a tissue to a second sample, where the first sample is a colonic tissue suspected of being neoplastic and the second sample is a normal human colonic tissue. The transcript is identified by a tag selected from AAX30947-31815. The methods of the invention can be used in the diagnosis, prognosis and
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Use of isolated gene transcripts - useful for developing products for the diagnosis, prognosis and treatment of cancers, particularly colon and pancreatic cancer.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Transcript tag sequence increased in pancreatic and colorectal cancer.

differentially expresent tag sequences of transcripts that are differentially expressed in colorectal cancer, in pancreatic cancer, or in both. The tag sequences can be used to identify genes by matching the tag to a gen data base member, or by using the tag sequences as probes to isolate unidentified genes from cDNA libraries. The tag sequences can also be used in a method for diagnosing colon or pancreatic cancer in a sample suspected of being neoplastic. The method comparises comparing the level of at least one transcript in a first sample of a tissue to a second sample, where the first sample is a colonic tissue suspected of being neoplastic and the second sample is a normal human colonic tissue. The transcript is identified by a tag selected from AAX30947-11815. The methods of the invention can be used in the diagnosis, prognosis and
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Use of isolated gene transcripts - useful for developing products for diagnosis, prognosis and treatment of cancers, particularly colon and pancreatic cancer.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Transcript tag sequence increased in pancreatic and colorectal cancer.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Tag sequence; colorectal cancer; pancreatic cancer; colon cancer; diagnosis; prognosis; treatment; ss.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      AAX30947-31815 represent tag sequences of transcripts that are differentially expressed in colorectal cancer, in pancreatic cancer, or in both. The tag sequences can be used to identify genes by matching the tag to a gen data base member, or by using the tag sequences as probes to isolate unidentified genes from cDNA libraries. The tag sequences can also be used in a method for diagnosting colon or pancreatic cancer in a sample suspected of being neoplastic. The method comprises comparing the level of at least one transcript in a first sample of a tissue to a second sample, where the first sample is a colonic tissue suspected of being neoplastic and the second sample is a normal human colonic tissue. The transcript is identified by a tag selected from AAX30947-31815. The methods of the invention can be used in the diagnosis, prognosis and
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Use of isolated gene transcripts - useful for developing products for the diagnosis, prognosis and treatment of cancers, particularly colon and pancreatic cancer.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Gaps

AAX30947-31815 represent tag sequences of transcripts that are differentially expressed in colorectal cancer, in pancreatic cancer, or in both. The tag sequences can be used to identify genes by matching the tag to a gen data base member, or by using the tag sequences as probes to
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      WPI; 1999-070161/06.

                                                                                                                                                                                                                                                AAX30947-31815 represent tag sequences of transcripts that are differentially expressed in colorectal cancer, in pancreatic cancer, or hotor. The tag sequences can be used to identify genes by matching the tag to a gen data base member, or by using the tag sequences as probes to isolate unidentified genes from cDNA libraries. The tag sequences can also be used in a method for diagnosing colon or pancreatic cancer in a sample suspected of being neoplastic. The method comprises comparing the level of at least one transcript in a first sample of a tissue to a second sample, where the first sample is a colonic tissue suspected of being neoplastic and the second sample is a normal human colonic tissue. The transcript is identified by a tag selected from AAX30947-31815. The methods of the invention can be used in the diagnosis, prognosis and
                                                                                                                                                                           Use of isolated gene transcripts - useful for developing products for the diagnosis, prognosis and treatment of cancers, particularly colon and pancreatic cancer.
                                                                                                                                                                                                                                                                                                                                                                                                                                                              Gaps

                                                                                                                                                                                                                                                   AAX30947-31815 represent tag sequences of transcripts that are differentially expressed in colorectal cancer, in pancreatic cancer, or moth both. The tag sequences can be used to identify genes by matching the tag to a gen date base member, or by using the tag sequences as probes to isolate unidentified genes from cDNA libraries. The tag sequences can also be used in a method for diagnosing colon or pancreatic cancer in a sample suspected of being neoplastic. The method comparises comparing the level of at least one transcript in a first sample of a tissue to a being neoplastic and the second sample is a colonic tissue suspected of being neoplastic and the second sample is a normal human colonic tissue. The transcript is identified by a tag selected from AAX30947-31815. The methods of the invention can be used in the diagnosis, prognosis and
Use of isolated gene transcripts - useful for developing products for the diagnosis, prognosis and treatment of cancers, particularly colon and pancreatic cancer.

isolate unidentified genes from cDNA libraries. The tag sequences can also be used in a method for diagnosing colon or pancreatic cancer in a sample suspected of being neoplastic. The method comprises comparing the level of at least one transcribt in a first sample of a tissue to a second sample, where the first sample is a colonic tissue suspected of being neoplastic and the second sample is a normal human colonic tissue. The transcript is identified by a tag selected from AAX30947-31815. The methods of the invention can be used in the diagnosis, prognosis and treatment of cancer.

Use of isolated gene transcripts - useful for developing products for diagnosis, prognosis and treatment of cancers, particularly colon and pancreatic cancer.

Claim 1; Page 53; 120pp; English.

differentially expresent tag sequences of transcripts that are differentially expressed in colorectal cancer, in pancreatic cancer, or in both. The tag sequences can be used to identify genes by matching the tag to a gen data base member, or by using the tag sequences as probes to isolate unidentified genes from cDNA libraries. The tag sequences can also be used in a method for diagnosing colon or pancreatic cancer in a sample suspected of being neoplastic. The method comparises comparing the level of at least one transcript in a first sample of a tissue to a being neoplastic and the second sample is a colonic tissue suspected of being neoplastic and the second sample is a normal human colonic tissue. The transcript is identified by a tag selected from hax30947-1815. The methods of the invention can be used in the diagnosis, prognosis and treatment

```
This sequence represents a peptide nucleic acid that can be used in the composition of the invention. The composition comprises at least 1 composition of the invention. The composition comprises at least 1 composition of the invention. The composition can be used at least 1 component (D) and acceptor (A) groups where at least 1 of the component polymers is a non-nucleic acid polymer. The compositions are particularly used to detect, identify or quantify nucleic acids that are present (or produced) in a closed tube assay, e.g. the product of an preferred applications are detecting viruses and other microorganisms of e.g. in foods, waters, pharmaceuticals, etc., including biological warfare agents); to determine effects of antimicrobial agents; for diagnosis of disease (e.g. genetic disorders such as cancer, thalassemia, cystic fibrosis etc.); for analysis/manipulation of plants and their genes, and in screening for potential drugs or factors that indicate succeptibility to drug interactions. Many different targets can be detected in a single reaction, using a common (AP)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Complex of probing and annealing polymers, labeled with donor and acceptor molecules, useful for detecting, identifying or quantifying target nucleic acids.
                                                                                                                                                                                                                                               Peptide nucleic acid; probing polymer; annealing polymer; detection; identification; virus detection; microorganism; antimicrobial agent; disease; genetic disorder; cancer; thalassemia; cystic fibrosis; ss.

This sequence represents a peptide nucleic acid that can be used in the composition of the invention. The composition comprises at least 1 probling polywer (PP), at least 1 annealing polywer (PP), at least 1 annealing polywer (PP) and acceptor (A) groups where at least 1 of the component polymers is a non-nucleic acid polymer. The compositions are particularly used to detect, identify or quantify nucleic acids that are present (or produced) in a closed tube assay, e.g. the product of an amplification reaction, or present in (living) cells or tissue. Some preferred applications are detecting viruses and other microorganisms (e.g. in foods, water, pharmaceuticals, etc., including biological warfare agents); to determine effects of antimicrobial agents; for diagnosis of disease (e.g. genetic disorders such as cancer, thalassemia, cystic fibrosis etc.); for analysis/manipulation of plants and their susceptibility to drug interactions. Many different targets can be detected in a single reaction, using a common (AP)

This sequence represents a peptide nucleic acid that can be used in the composition of the invention. The composition comprises at least 1

probing polymer (PP), at least 1 annealing polymer (AP) and at least 1

set of donor (D) and acceptor (A) groups where at least 1 of the component polymers is a non-nucleic acid polymer. The compositions are particularly used to detect, identify or quantify nucleic acids that are present (or produced) in a closed tube assay, e.g. the product of an present (or produced) in a closed tube assay, e.g. the product of an preferred applications are detecting viruses and other microorganisms (e.g. in foods, water, pharmaceuticals, etc., including biological warfare agents); to determine effects of antimicrobial agents; for diagnosis of disease (e.g. genetic disorders such as cancer, thalassemia, cystic fibrosis etc.); for analysis/manipulation of plants and their cystic fibrosis etc.); for analysis/manipulation of plants and their custofillity to drug interactions. Many different targets can be detected in a single reaction, using a common (AP)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              ö

This sequence represents a peptide nucleic acid that can be used in the composition of the invention. The composition comprises at least 1 problems (PP), at least 1 annealing polymer (PP), at least 1 annealing polymer (PP), at least 1 annealing polymer (PP) and at least 1 set of donor (D) and acceptor (A) groups where at least 1 of the component polymer is a non-nucleic acid polymer. The compositions are particularly used to detect, identify or quantify nucleic acids that are present (or produced) in a closed tube assay, e.g. the product of an amplification reaction, or present in (living) cells or tissue. Some preferred applications are detecting viruses and other microorganisms (e.g. in foods, water, pharmaceuticals, etc., including biological warfare agents); to determine effects of antimicrobial agents; for diagnosis of disease (e.g. genetic disorders such as cancer, thalassemia, cystic fibrosis etc.); for analysis/manipulation of plants and their cystic fibrosis etc.); for analysis/manipulation of plants and their susceptibility to drug interactions. Many different targets can be cheected in a single reaction, using a common (AP)
                                                                                                                                                                                                                                                                                                                                                                                                                /*tag= a

This sequence represents a peptide nucleic acid that can be used in the composition of the invention. The composition comprises at least 1 probling polyware (PP), at least 1 annealing polyware (PP), at least 1 annealing polyware (PP), at least 1 annealing polyware (PP) and acceptor (A) groups where at least 1 of the component polymers is a non-nucleic acid polymer. The compositions are present (or praticularly used to detect, identify or quantify nucleic acids that are present (or produced) in a closed tube assay, e.g. the product of an amplification reaction, or present in (living) cells or tissue. Some preferred applications are detecting viruses and other microorganisms (e.g. in foods, water, pharmaceuticals, etc., including biological warfare agents); to determine effects of antimicrobial agents; for diagnosis of disease (e.g. genetic disorders such as cancer, thalassemia, cents fibrosis etc.); for analysis/manipulation of plants and their genes, and in screening for potential drugs or factors that indicate a susceptibility to drug increatchose. Many different targets can be detected in a single reactions. Many different targets can be
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Complex of probing and annealing polymers, labeled with donor and acceptor molecules, useful for detecting, identifying or quantifying target nucleic acids.
                                                                                                                                                                                                                                                                      Peptide nucleic acid; probing polymer; annealing polymer; detection; identification; virus detection; microorganism; antimicrobial agent; disease; genetic disorder; cancer; thalassemia; cystic fibrosis; ss.

```
This sequence represents a peptide nucleic acid that can be used in the composition of the invention. The composition comprises at least 1 probing polymer (PP), at least 1 annealing polymer (AP) and acceptor (A) groups where at least 1 of the component polymers is a non-nucleic acid polymer. The compositions are particularly used to detect, identify or quantify nucleic acids that are present (or produced) in a closed tube assay, e.g. the product of an amplification reaction, or present in (living) cells or tissue. Some preferred applications are detecting viruses and other microorganisms (e.g. in foods, water, pharmaceuticals, etc., including biological warfare agents); to determine effects of antimicrobial agents; for diagnosis of disease (e.g. genetic disorders such as cancer, thalassemia, cystic fibrosis etc.); for analysis/manipulation of plants and their susceptibility to drug interactions. Many different targets can be detected in a single reaction, using a common (AP)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Complex of probing and annealing polymers, labeled with donor and acceptor molecules, useful for detecting, identifying or quantifying target nucleic acids.
                                                                                                                                                                                                                                                        Peptide nucleic acid; probing polymer; annealing polymer; detection; identification; virus detection; microorganism; antimicrobial agent; disease; genetic disorder; cancer; thalassemia; cystic fibrosis; ss.

capable of modulating a process in a biological system. The method capable of modulating a process in a biological system. The method compaintses: (a) introducing into the system a random library of nucleic acid catalysts (NAC) having a substrate binding domain (SBD), comprising a random sequence, and a catalytic domain (CD); and (b) identifying NAC in systems where modulation has occurred and/or determining the sequence of at least part of the SBDs in such systems. Nucleic acid molecules with endonuclease activity and catalytic activity, from the present invention, are used to modulate gene expression in plant and mammalian cells and to cleave target nucleic acid, particularly for treating systems. Our acceptance of a caused by specific RNA, e.g. cancer, inflammation, psoriasis, non-hepatic ascites and infection. They may also be used to detect genetic drift and ascites and infection. They may also be used to detect genetic drift and ascites and infection accer, includate expression of the Raf gene, are used to treat cancer, restenosis, psoriasis or rheumatoid arthritis, or generally any condition associated with the level of c-raf. Introduction of suchivity. AAV90922 to AAV93877 represent NACs that can be used in the method, specifically for modulating the expression of a Raf gene
                                                                                                                                                                                                                                                                           Human, c-raf, A-raf, B-raf, hammerhead ribozyme, hairpin ribozyme,

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          The invention is directed to methods, kits and compositions pertaining to linear Beacons. It provides novel polymers that comprise at least one linear Beacons. It provides novel polymers that comprise at least one linked donor moiety, at least one linked acceptor moiety where the donor and acceptor moieties are separated by a nucleobase sequence (NBS) and where the polymer does not form a stem and loop hairpin and is further characterized in that the efficiency of transfer of energy between the donor and acceptor moieties when the polymer is solvated in aqueous solution is independent of at least 2 variables selected from: (a) NBS length; (b) spectral overlap of the donor moiety and the acceptor moiety; (c) presence or absence of magnesium in the aqueous solution; and (d) ionic strength of the aqueous solution. The polymers earthouture such that upon hybridisation to a target sequence the efficiency of energy transfer between the donor and acceptor moieties is altered such that upon hybridisation and acceptor moieties is altered such quantitate occurrence of the hybridisation event. The polymers can be used to detect organisms in e.g. food, beverages, water, pharmaceutical,

personal care products, dairy products or environmental samples. They can be used to examine clinical samples such as clinical specimens or equipment, fixtures and products used to treat humans or animals. They can also be used to detect a target sequence which is specific for a genetically based disease, e.g. beta-thalassemia, sickle cell amemia, Factor-V Leiden, cystic fibrosis and cancer related targets such as p55, p10, BRC-1 and BRC-2. They can also be used to detect a target sequence in a formacic technique such as prenatal screening, paternity testing, identity confirmation or crime investigation. Sequences AAX82052-56 represent DNA probe sequences which are of equivalent subunit length to linear baccons and is used to exemplify the method of the invention
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         The invention is directed to methods, kits and compositions pertaining to Linear Beacons. It provides novel polymers that comprise at least one linked donor moiety, at least one linked acceptor moiety where the donor and acceptor moiety where the annotative are separated by a nucleobase sequence (NBS) and
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Linear Beacon; polymer; nucleobase sequence; hybridisation; signal; energy transfer; organism detection; pharmaceutical; beta-thalassemia; nucleic acid detection; sickle cell anemia; Factor-V Leiden; cancer; cystic fibrosis; forensic; prenatal screening; paternity testing; probe;

cc where the polymer does not form a stem and loop hairpin and is further characterized in that the efficiency of transfer of energy between the donor and acceptor moieties when the polymer is soluted in aqueous solution; is independent of at least 2 variables selected from: (a) NBS length; (b) spectral overlap of the donor moiety and the acceptor moiety; (c) presence or absence of magnesium in the aqueous solution; and (d) conic strength of the aqueous solution. The polymers have a structure such that upon hybridisation to a target sequence the efficiency of energy transfer between the donor and acceptor moieties is altered such that detectable signal from at least one moiety can be used to courrence of the hybridisation event. The polymers can be used to detect organisms in e.g. food, beverages, water, pharmaceutical, personal care products dairy products or environmental samples. They can also be used to examine clinical samples such as clinical samples. They can also be used to detect a target sequence which is specific for a genetically based disease or is specific for a predisposition to a genetically based disease, e.g. beta-rhaiassemia, sickle cell anemia, rector-V Leiden, cystic fibrosis and cancer related targets such as p55, p10, BRC-1 and BRC-2. They can also be used to detect a target sequence of an also be used to crime investigation. Sequences AAX82052-56 represent DNA probe sequences which are of equivalent subunit length to linear baecons and is used to exemplify the method of the invention \$

Protection of plants including tomato, pepper, lettuce, radish, parsley, sugar beat, rape, and onions against pathogenic fungi, uses a binucleate Rhizoctonia strain for biocontrol.

```
The invention relates to a novel method of protecting plants from pathogenic fungi. The method comprises biocontrol of pathogenic fungi via the use of a non-pathogenic, binucleates Rhizoctonia is selected by modecular detection of certain binucleate Rhizoctonia is selected by modecular detection of certain internal transcribed spacer (ITS)-5.8 ribosomal DNA sequences (AAZ93445-CC AAZ9245), which vary between strains of these fungi. The invention also encompasses a concentrate for use in plant protection containing viable primerial from the binucleate Rhizoctonia strains of the invention, and primer invention are used as biocontrol agents for related pathogenic fungi. Binucleate Rhizoctonia isolate Eab-F2 was tested for its ability to consecutively (the binucleate Eab-F2 was tested for its ability to consecutively (the binucleate strain sere inculated either simultaneously or consecutively (the binucleate strain followed by the pathogenic strain), consecutively (the binucleate strain followed by the pathogenic strain), conficulation), whereas no protection was provide protection against the pathogenic strain when it had been allowed to colonise the vegetal surface. The binucleate strain was provided when both strains were inoculated simultaneously. The method of the invention may be used to inoculate and alfalfa, trees and ornamental plants. The method is crealable and provides variety of plants from pathogenic fungal infected rape, crealable and provides economical biocontrol of diseases caused by the may be used to identify and distinguish strains of Rhizoctonia solani. Sequences, thereby classifying their pathogenicity

The present sequence represents the preferred target sequence of an enzymatic nucleic acid, especially a hammerhead ribozyme, which cleaves the describtor line. (HCV) RNA sequence at the base position given in the describtor line. The HCV sequence was screened for optimal ribozyme is target sites using a computer folding algorithm and regions of the make which did not form secondary folding structures and contained potential ribozyme cleavage sites were identified. Ribozymes were synthesised to target these sites and their activities optimised by either varying the rarget of the binding arms or by modification to prevent degradation by nucleases. The ribozymes of the invention inhibit gene expression and/or viral replication, and are used to treat diseases associated with hepatocellular carcinoma: The ribozymes may be used in combination with interferon to treat HCV infection, other infectious diseases, autoimmune Claim 1; Page 78; 123pp; English. ribozymes for th tis C infection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               The present sequence represents the preferred target sequence of an enzymatic nucleic acid, especially a hammerhead ribozyme, which cleaves the Hepatitis C virus (HCV) RNA sequence at the base position given in the descriptor line. The HCV sequence was screened for optimal ribozyme target sites using a computer folding algorithm and regions of the mRNA which did not form secondary folding structures and contained potential ribozyme cleavage sites were identified Rhozymes were synthesised to target these sites and their activities optimised by either varying the length of the binding arms or by modification to prevent degradation by nucleases. The ribozymes of the invention inhibit gene expression and/or viral replication, and are used to treat diseases associated with Hepatitis C virus (HCV) infection, e.g. cirrhosis, liver failure and cheated expression to treat HCV infection, other infectious diseases, autoimmune cancer.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       ö

The invention relates to the isolation of sequences encoding human haemopoietin receptor protein family NR8 genes. The NR8 family sequences were initially searched for comparison on a nucleic acid database with the nucleic acid probe sequence TGGAGYNNNTGGAGY encoding the amino acid sequence Trp-Ser-Xaa-Trp-Ser. The sequences AAZ59258-Z59300 and AAZ90816-Z99925 represent specific examples of probe sequences used in the search. Antibodies to the NR8 family proteins are used for the diagnosis of blood formation disorders. Compounds identified as binding to the proteins are used for the treatment of such disorders
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               The invention relates to the isolation of sequences encoding human haemopoietin receptor protein family NR8 genes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    셤
                                                                                                                                                                                                                                                                                                                                                                                                                                                          ò
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                          The invention relates to the isolation of sequences encoding human haemopoietin receptor protein family NR8 genes. The NR8 family sequences were initially searched for comparison on a nucleic acid database with the nucleic acid probe sequence TGGAGYNNNTGGAGY encoding the amino acid sequence Trp-Ser-Xaa-Trp-Ser. The sequences AAZ59258-Z59300 and AAZ90816-Z9025 represent specific examples of probe sequences used in the search. Antibodies to the NR8 family proteins are used for the diagnosis of blood formation disorders. Compounds identified as binding to the proteins are used for the treatment of such disorders
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Hemopoietin receptor protein family NR8 used for diagnosis of blood formation disorders.
                                                                                                                                                                                                                                                                                                                                                        Hemopoietin receptor protein family NRB used for diagnosis of blood formation disorders.

The invention relates to the isolation of sequences encoding human haemopoietin receptor protein family NR8 genes. The NR8 family sequences were initially searched for comparison on a nucleic acid database with the nucleic acid probe sequence TGGAGYNNNTGGAGY encoding the amino acid sequence Trp-Ser-Xaa-Trp-Ser. The sequences AAZ59258-Z59300 and AAZ90816-Z9025 represent specific examples of probe sequences used in the search. Antibodies to the NR8 family proteins are used for the diagnosis of blood formation disorders. Compounds identified as binding to the proteins are used for the treatment of such disorders
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Lentivector; polypurine tract; PPT; gastrointestinal disease; cancer; inflammation; glandular disease; renal disease; dermal disease; autoimmune disease; neurodegenerative disease; transplantation; ds.
                                                                                                                                                                                                                                                                                                                                                     Hemopoietin receptor protein family NR8 used for diagnosis of blood formation disorders.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Rohll J, Kingsman SM, Kingsman AJ;

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              The invention relates to the isolation of sequences encoding human haemopoietin receptor protein family NR8 genes. The NR8 family sequences were initially searched for comparison on a nucleic acid database with the nucleic acid probe sequence TGGAGYNNNTGGAGY encoding the amino acid sequence Trp-Ser-Xaa-Trp-Ser. The sequences AAZ59258-Z59300 and AAZ90816-Z9025 represent specific examples of probe sequences used in the search. Antibodies to the NR8 family proteins are used for the diagnosis of blood formation disorders. Compounds identified as binding to the proteins are used for the treatment of such disorders

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     K-ras, electrostatic, polyethylene imine, PEI; bead; matrix, peptide-nucleic acid; PNA; analysis; point mutation; prenatal screening; paternity testing; identity confirmation; crime investigation; ss.
                                                                                                                                       The present sequence is a potential polypurine tract sequence (PPT). The modification of this type of sequence has been shown to optimise the performance of lentiviral vectors. Retroviral based vectors can be used in the gene therapy of many diseases, including cancer, inflammatory diseases such as rheumatoid arthritis and systemic lupus erythematosus, cardiac arrest, myocardial infraction, diseases of the gastrointestinal tract, glandular diseases, renal diseases, dermal diseases, infertility, disease, antoimmune diseases, parkinson's disease, Alzheimer's disease, Down's syndrome, infectious diseases, and complications due to transplantation or gene therapy
                                             Retroviral vectors with increased titre and transduction ability for use in medicine, especially gene therapy comprises a plus-stranded synthesis
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                /*tag= b

acide which had been electrostatically bound to polyethylane imine (PEI)
acide which had been electrostatically bound to polyethylane imine (PEI)
acide which had been electrostatically bound to polyethylane imine (PEI)
acide which had been electrostatically detected using labeled peptide-
nucleic acid (PNA) probes where the labeled (neutral) PNA would not
become immobilized to the beads in the absence of target nucleic acid,
become immobilized to the beads in the absence of target nucleic acid,
become immobilized to the beads in the absence of target nucleic acid,
become immobilized to the beads in the become immobilized to the beads, if the
target nucleic acid was present. The DNA templates for PCR were the human
base 129 (see AAA29027-28). Novel compositions comprise a matrix, a
target nucleic acid sequence which is electrostatically hybridizes to a
natrix and a non-nucleotide probe which specifically hybridizes to a
complexes can be detected, identified or quantitated under a wide range
of assay conditions. Reversible binding allows the complex to be removed
from the matrix for analysis. The method is rapid, sensitive, reliable
and versatile in detecting target sequences which are particular to
organisms found in fecod, beverages, water and pharmaceutical products.
The non-nucleotide probe/target sequence is protected against degrade
conganisms contained by ample can be treated with enzymes to degrade
sample contaminants. The methods, etc. are especially useful for
detection of single point mutations, and hence analysis of a genetically
be assed disease and in forensic techniques such as prenatal screening,
containing testing, identity confirmation or crime investigation
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     ö

AAA AAA29016-26 were used to examine whether the presence of target nucleic acids which had been electrostatically bound to polyethylene imine (PEI) decide which had been electrostatically be acids using the decide desired begins a considerable of the beads could be specifically detected using labeled peptidenucle acid (PNA) probes where the labeled (neutral) PNA would not become immobilized to the beads in the absence of target nucleic acid, become immobilized to the beads, if the target nucleic acid was present. The DNA templates for PCN were the human K-ras gene and a mutant K-ras gene, which contains a point mutation at the assence and a mutant K-ras gene, which contains a point mutation at the assence and a non-nucleotide probe which specifically hybridizes to a portion of one or more target sequences. Immobilized probe/target complexes can be detected, identified or quantitated under a wide range of assay conditions. Reversible binding allows the complex to be removed from the matrix for analysis. The method is rapid, sensitive, reliable and versatile in detecting target sequences which are particular to organisms found in food, beverages, water and pharmaceutical production probe/target sequences which are particular or organisms and hence the sample can be treated with enzymes to degrade sample contaminants. The methods, ere especially useful for detection of single point mutations, and hence analysis of a genetically based disease and in forensic techniques such as prenatal screening, beach assenting testing, identity confirmation or crime investigation Composition for identifying target sequence of nucleic acids for detecting genetic-diseases and pathogens in food and water, comprises non-nucleotide probe which sequence specifically hybridizes to target /note= "optionally Adenine-Lysine(dabcyl) for probe BK-Ras-Cy3" 0.5%; Score 10.8; DB 1; Length 15; 85.7%; Pred. ```
The present sequence is a mutated allele-specific oligonucleotide probe for the G590A mutation in the N-acetyltransferase 2 (NAT2) gene. NAT2 is a sanobiotic-metabolishing enzyme. This probe can be used to determine the genotype of an individual at the nat2 locus, and thus determine their susceptibility to toxicity associated with certain drugs, and to certain
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Osteogenic protein-1; OP-1; morphogenic protein; mouse; osteoporosis; morphogen concentration; bone metabolism disease; ss.

N-acetyltransferase 2 G590A mutant ASO probe.

expression by incubating a candidate compound with a nucleic acid with a reporter gene operatively associated with an OP-1 non-coding nucleic acid fragment

Disclosure; Col 47; 33pp; English.

the expression of osteogenic protein-1 (OP-1) uses a cell transfected the expression of osteogenic protein-1 (OP-1) uses a cell transfected with a nucleic acid sequence comprising a reporter gene and an upstream non-coding sequence from OP-1. OP-1 is a tissue morphogenic protein. The method is useful for screening compounds capable of stimulating or The compounds which may be used as therapeutics for in vivo and ex vivo mammalian applications, e.g. morphogen expression inducing compounds for correcting and alleviating a diseased condition or to regenerate lost or damaged tissue. The compounds may also be used to maintain viability of the differentiated phenotype of cells in culture. Morphogen expression inhibiting compounds identified by the new method can be used to condulate the degree and/or timing of morphogen concentration. Compounds which upcredulate levels of circulating OP-1 in vivo can be used to correct bone corrections may also be used to seed to correct bone corrections diseases such as osteoporosis. This sequence cortained in the upstream region of the osteogenic protein-1 (OP-1) gene. The DNA binding commence at these sites and control transcription of DNA protein. sequences at these sites

Simple, rapid and accurate method for distinguishing HLA class I allele type with possibility of mechanization and automation, applicable in judging donor-recipient compatibility during organ transplant and disease diagnosis.

Claim 8; Page 50; 83pp; Japanese

The present invention describes a method for distinguishing a human leukocyte antigen (HLA) class I antigen or allele by a combination of polymerase chain reaction (PCR) using a primer pair whereby all HLA-A, -B or -C alleles can be amplified or using reverse hybridisation analysis comprising a DNA probe covalently bonded to microtitre plate wells which are hybridisable specifically with the base sequence of at least one specific HLA-A. B or -C allele. The method is applicable in gene typing, judging donor-recipient compatibility during organ transplant and correlation analysis for diagnosis of various diseases. The method is simple, rapid and accurate, with possibility of mechanisation and automation, without the problems encountered by using the prior-art techniques. AAA66943 to AAA67072 represent oligonucleotide probes and PCR primers for use in the method of the present invention

Determining presence or absence of a predetermined endogenous nucleic acid sequence by using an enzyme that depolymentizes the 3' end of an oligonuclectide probe hybridized to a target sequence to release identifier nucleotides.

Example; Page 373; 389pp; English.

The present invention describes a method (MI) for determining the presence or absence of a predetermined endogenous nucleic acid target sequence (ENAT). The method comprises hybridising a probe having an identifier nucleotide (IN) with ENAT which is treated with an enzyme that depolymerises the 3' and of hybridised NA to release the INS. MI is used for determining the number of known sequence repeats present in a nucleic

acid target sequence in a nucleic acid sample. The method is also useful for determining whether a nucleic acid target sequence in a sample is an allele from a homozygous or heterozygous locus. The method is also useful for detection of mutations, remaislocations and SNPs in nucleic acids (including those associated with genetic disease), determination of viral foreisic samples. AAA86791 to AAA87079 and AAB12817 represent sequence which are used in the exemplification of the present invention. N.B. here is a discrepancy between the SEQ ID NO: and sequences given in the examples, and the SEQ ID NO: and sequences given in the from the present invention

Detecting a chromosome 1q21-q24 abnormality for diagnosing metabolic disease, such as human obesity and diabetic disorders, comprises examining insulin receptor-related receptor gene and its gene products.

Claim 10; Page 43; 111pp; English.

The present invention relates to insulin receptor-related receptor (IRRR). Mutations in this gene indicate a chromosome 1q21-q24 abnormality. IRRR polypeptides and DNA may be useful in the diagnosis of of disorders associated with abnormal expression of the IRRR protein, for example obesity, dyslipidemia and diabetes

Determining the concentration of a target nucleic acid, useful e.g. for detecting genetic mutations, comprises using a fluorescently labeled probe in which emission is reduced by binding to the target nucleic acid.

Example 7; Page 24; 55pp; English.

The invention relates to the determination of the concentration of a nucleic acid target, using a fluorescently labeled probe which produces creduced fluorescence emission when hybridisate to the target nucleic acid. The method comprises measuring the reduction in emission caused by the method comprises chain reaction, e.g. for the nucleic acids by a real-time polymerase chain reaction, e.g. for curcial acids to polymorphisms, and for analysing melting detecting gene mutations or polymorphisms, and for analysing melting curves of target nucleic acids to determine a Th value. Methods of the convention allow target nucleic acids to determine a Th value. Methods of the convention allow target nucleic acids to be quantified quickly, easily and accurately. Particularly there is no need to remove unbound probe, and of accurately. Particularly there is no need to remove unbound probe, and of accurately. Particularly there is no need to remove unbound probe, and accurately are introduced that inhibit amplification by Tag polymerase (so conventional Pork conditions can be used). The specificity of PCR is kept working and the limit of authoritation is reduced. Complex probes are not needed, and amplification can be mentioally generated by a computer) has a higher correlation coefficient than conventional graphs so more accurate quantitation is coefficient than conventional graphs so more accurate quantitation is coefficient than conventional graphs so more accurate quantitation is invention that was used for investigating the effects of the kinds of the bases in each target nucleic acid, and the kind of bases in its

The present invention relates to the human uncoupling protein 3 mitochondrial, proton carrier) (UCP3) gene and polymorphisms. The polymorphisms are associated with obesity, especially diabetes mellitus associated obesity. They polymorphisms may be identified and analysed to determine whether an individual is susceptible to obesity and may be used as the basis for targeted design of drugs to treat obesity. The present sequence was used in the identification and amplification of UCP3
                                                                                                                                                      UCP3; uncoupling protein 3; polymorphism; obesity; diabetes mellitus; ss.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Involves amplifying the nucleic acid sequences in a sample involves amplifying the nucleic acid sample by PCR and then cleaving the amplified products with uracil DNA glycosylase (UDG), the resulting DNA camplified products with uracil DNA glycosylase (UDG), the resulting DNA regeners blot hybridisation techniques. The method can be used to distinguish between two different sequences, for example for the detection of a DNA fragment carrying a mutation. The method is useful for detection of a DNA fragment carrying a mutation. The sequence containing a polymorphic restriction site associated with a diseases such as cystic fibrosis disease, and may be used for detecting infectious diseases. Genetic disorders such as sickle cell anaemia, cystic fibrosis, alpha or beta thalassaemia, muscular dystrophy, and Tay-Sachs disease may also be detected using the method. Oncogenes such as Sachs disease may also be detected using the method. Oncogenes such as cancers. The present sequence represents a fragment of the cystic fibrosis (CF) gene created by UDG cleavage. This sequence is used in an example of the invention and contains the position of a mutation site in themmet (AAA.7261) can be used to produce probes specifically to identify the mutation, which can then be used in the method of the
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Detecting specific nucleic acid sequence in sample containing nucleic acids involves amplifying nucleic acid, cleaving amplified products with uracil-DNA glycosylase to obtain DNA segments and detecting segments.
                                                                                                                                                                                                                                                                  Uracil DNA glycosylase; UDG; infectious disease detection; cancer; sickle cell anaemia; cystic fibrosis; thalassaemia; muscular dystrophy; Tay-Sachs disease; ss.

The sequence represents an allele specific oligonucleotide probe for acetylcholine receptor. CHMR1. CHMR1 is one subtype of a family of 5 genetically distinct muscarinic acetylcholine receptors, mAChR, that play important roles in higher brain function such as learning and memory. The protein is a possible drug target for treatments for Alzheimer's disease and antibodies raised against the protein are useful for diagnosing and expression of the gene or activity of the protein, e.g. Alzheimer's disease developing treatments for diseases associated with the abnormal expression of the gene or activity of the protein, e.g. Alzheimer's disease and dementia with Lewy bodies
                                                                                                                               New variants of the ml muscarinic acetylcholine receptor gene, useful find treatment for Alzheimer's and dementia, have single nucleotide variations at one or more of five polymorphic sites.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Polynucleotide mutations that confers resistance to paclitaxel for detecting paclitaxel-resistant cells in tumor biopsies from patients receiving paclitaxel therapy.
                                                                                                                                                                                                                                                                                                                                                                                                                            ch 0.5%; Score 10.8; DB 1; Length 15; 1 Similarity 85.7%; Pred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      nucleotide sequence which is a polymorphic variant of the fully defined 7821 base pair interleukin-1 beta (ILIB) gene reference sequence given in the specification or its fragment or complement. The ILIB gene expression and polymorphic variant is useful for therapeutic purposes, for studying the expression and biological function of ILIB, for developing drugs may roctean, and in diagnostics and forensic applications. The method is useful for developing tests and therapeutic treatments for inflammatory and immune disorders. The present sequence is an allele-specific oligonucleotide (ASO) probe for detecting ILIB gene
                                                                                                                                                                                                                             ô
sensitivity in a sample from a cancer patient and for determining paclitaxel sensitivity in a sample from a cancer patient and for determining suitable therapeutics to treat cancer patients. If a mutation in the H6H7 region of tubulin is present then a non-pactitaxel oncologic medication that is an antimitotic drug which inhibits microtubule assembly is given Resistance of tumor cells or patients to drugs which affects microtubule assembly can be determined with the use of mutations in H6H7 region of
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       New polynucleotide useful for therapeutic purposes, comprises nucleotide

Novel polymorphic variant of reference sequence for human cholinergic receptor, muscarinic 3 gene, useful for diagnostic and therapeutic purposes.

Claim 15; Page 19; 54pp; English.

The patent relates to polymorphic variants of human cholinergic receptor, muscarinic 3 (CHRM3) gene. The polymorphic variant comprises at least one single nucleotide polymorphism selected from cytosine at PS4. adenine at PS2 or PS3, and cytosine at PS4. The invention also relates to a method for genotyphing and haplotyphing the CHRM3 gene for identification of variants. The polymorphic variant is useful for therapeutic purposes. for studying the expression and biological function of CHRM3, as well as for developing drugs targetting the CHRM3 protein. The variant is also useful in diagnostics and forensic applications. The recombinant nonhuman corganism transfected with the polymorphic variant is useful for studying expression of CHRM3 isogenes in vivo, for in vivo screening and testing of therapeutic agents and compounds for Alzheimer's disease, Sjogren's syndrome, disorders associated with smooth muscle contractility and sudden infant death syndrom the CHRM3 protein variant is useful in drug screening assays and its antibodies are useful in immunoassays to detect CHRM3 protein variants in biological samples. The present sequence is an allow of the specific oliginucleotide (ASO) primer used for detecting human CHRM3 gene polymorphism

New human death-associated protein 6 (DAXX) gene variants comprising 19 polymorphic sites useful in studying the effect of variation on the biological activity of DAXX and in developing drugs targeting the protein.

Claim 15; Page 18; 97pp; English.

Sequences AASO4300-AASO4337 represent oligonucleotide probes specific for a DNA encoding human death-associated protein 6 (DAXX). This DNA may comparise one or more polymorphisms at specific nucleotide positions to comparise one or more polymorphisms at specific nucleotide positions between form one of nineteen possible polymorphic variants. Associations between a trait and a genotype or a haplotype of the DAXX gene can be identified by comparing the frequency of the genotype in a population can exhibiting the trait with that of a reference population. A higher frequency in the trait population indicates an association. Methods involving genotyping or haplotype pairs for the DAXX gene of an individual can lead to prediction of haplotype pairs for the DAXX gene of related individuals, and may be useful in studying the expression and biological individuals, and may be useful in studying the effect of the PAXX are useful in studying the effect of the colymorphic variants of DAXX are useful in studying the effect of the affinity of candidate drugs targeting DAXX as well as not the binding affinition diversity, anthropological lineage, autoimmume diseases and other immume diseates. Polymorphism is also useful for studying population diversity, anthropological lineage, paternity testing, forensic applications, and for identifying confidence the DAXX genetic variation and a trait such as level to measure binding affinities of one or more candidate drugs targeting the banks and the banks. the DAXX protein

Sequences AASO4300-AASO4337 represent oligomucleotide probes specific for a DNA encoding human death-associated protein 6 (DAXX). This DNA may comparise one or more polymorphisms at specific nucleotide positions to form one of nineteen possible polymorphic variants. Associations between a trait and a genotype or a haplotype of the DAXX gene can be identified by comparing the frequency of the genotype of the polymorphic nation. A higher can exhibiting the trait population indicates an association. Methods involving genotyping or haplotype pairs for the DAXX gene of an individual can lead to operation of haplotype pairs for the DAXX gene of an individual can individuals, and may be useful in studying the expression and biological function of DAXX, as well as in developing drugs targeting this protein. Polymorphic variants of DAXX are useful in studying the effect of the variation on the biological activity of DAXX as well as on the binding affinity of candidate drugs targeting DAXX as well as not be binding affinity of candidate drugs targeting DAXX as well as in a sociations to the binding associations between the DAXX genetic variation and or studying population diversity, anthropological lineage, paternity testing, forensic applications, and for identifying to drug response or susceptibility to disease. DAXX proteins may be used the DAXX genetic variation and a trait such as the DAXX proteins may be used the DAXX genetic variation and a trait such as the DAXX proteins.

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonuclectide, (for Insulin-like Growth Factor [1679]-1 receptor, 1978 binding protein [16789]-2 or 167893), which is capable of inhibiting or reducing prowth factor mediated cell proliferation.

In consideration and/or other disorders. The present sequence is an oligonuclectide which can be used to design the antisense oligonuclectide which can be used to design the antisense oligonuclectide with a method is useful for ameliorating the effects of psoriasis, conthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, karacoais, conthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, karacoais, conthyosis, pityriasis, warts, benign growths, cancers of the skin, a phyperneovascular condition such as a neovascular condition of the skin, a brian or skin, growth factor-mediated malignancies, other sclerotic condition of the inside of blood
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     ö

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an anticonters. The method comprises contacting the skin with an anticonters. Glogonucleotide, [for Insulin-like Growth Factor Insell.]

Treceptor, IGF binding protein [IGFB9]-2 or IGFB93), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the antisense oligonucleotide of the present invention (see AAF45151 and AAF45153-F45161). The method is useful for ameliorating the effects of psoriasis, cothyposis, pityriasis, ruba, pilaris, serborthoea, keloids, keratosis, noplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, chean or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood consequence.

Edmondson (MURD-) MURDOCH CHILDRENS RES INST. 21-JUN-1999; 99US-0140345P. 21-JUN-2000; 2000WO-AU000693 Wnaight CJ, Werther GA, WPI; 2001-041421/05. WO20007B341-A1. Homo sapiens. 28-DEC-2000.

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleoride, (for Insulin-like Growth Factor [IGR]-1 receptor, IGF binding protein [for Insulin-like Growth Factor [IGR]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the antisense oligonucleotide which can is useful for ameliorating the effects of psoriasis, inthyosis, pityriasis, ruba, pitaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, branch or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperplasia

                                                    The present invention relates to a method for ameliorating the effects of akin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGF] receptor, IGF binding protein [IGFBP] to IGFBP3), which is capable inhibiting or reducing growth factor mediated cell proliferation, inhibiting or reducing growth factor mediated cell proliferation, oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF4151 and AAF45153-6150nucleotides of the present invention growths, cancers of the skin, a hyperance ondition such as a necessor such skin, a prowth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Gaps

The present invention relates to a method for ameliorating the effects of skin discoders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGR]) receptor, IGF binding protein [IGRBP]-2 or IGFBB3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF45151 and AAF45153-Glounthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, inhthyosis, pityriasis, una, plaris, serborrhoea, keloids, keratosis, inhthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other scleroic
                                                                                                                                                                                                                                                                          Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [167]) receptor, 167 binding protein [16828]-2 or 167839; which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF4151 and AAF45153-F45161). The method is useful for ameliocating the effects of psoriasis, ichthyosis, pityriasis, ruba, pliaris, serborrhoea, keloids, keratosis, hyperneovascular condition such as a neovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic vessel or and a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic vessel or a new order of the inside of blood disease, kidney disease, nyperplasia vessels or any other hyperplasia

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation.

Example 8; Page 72; 201pp; English.

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonuclectide, (for Insulin-like Growth Factor [IGR]-1 ceceptor, IGF binding protein [IGFB]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, of inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonuclectide which can be used to design the antisense oligonuclectides of the present invention (see AAP45151 and AAP45153-F45161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serborthoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, disease, kidney disease, hyperproliferation of the inside of blood tessels or any other hyperplasia

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or infiammation.

```
The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGR]-1 receptor, IGF binding protein [IGRB]-2 or IGRBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, of inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the affects of psoriasis, P45161). The method is useful for ameliorating the effects of psoriasis, nechthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, disease, kidney disease, hyperproliferation of the inside of blood vessels or any other hyperplasia
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Sequence 15 BP; 7 A; 4 C; 4 G; 0 T; 0 U; 0 Other;

WPI; 2001-041421/05.

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation.

Example 7; Page 45; 201pp; English.

effects of The present invention relates to a method for ameliorating the efskin disorders. The method comprises contacting the skin with an schultz451-1.rng

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGR]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or
antisense oligonucleotide, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFB3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see ARF45131 and AAF45153-F45161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other selerotic disease, kidney disease, hyperproliferation of the inside of blood
                                                                                                                                                                                                                                                                                                                                                                                            Gaps
                                                                                                                                                                                                                                                                                                                                                                                              ;

The method comprises contecting the skin with an antisense oligomucleotide (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBPB), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligomucleotide which can be used to design the antisense oligomucleotides of the present invention (see AAF45151 and AAF45153-F45161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Antisense therapy, antiproliferative, antiinflammatory; antipsoriatic; cytostatic; dermatological; cardiant; virtucide; ophthalmological; keloid; skin disorder; Insulin-like Growth Factor I receptor; IGF-1; pityriasis; IGF binding protein; IGFBP-2; IGFBP3; inflammation; psoriasis; pilaris; growth factor mediated cell proliferation; ichthyosis; serborrhoea; ruba; keratosis; neoplasia; sclerofarma; wart; skin cancer; sclerotic disease; hyperneovascular condition; hyperplasia; kidney disease;
oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF45151 and AAF45153 - p45161). The method is useful for ameliotrating the effects of psoriasis, ichthyosis, pityriasis, tuba, pilaris, serborthoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, tidney disease, hyperproliferation of the inside of blood

Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation.

Example 6; Page 38; 201pp; English.

Example 8; Page 93; 201pp; English.

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antidomorphy contacting the skin with an antidomorphy (for Insulin-like Growth Pactor [IGR]-1 receptor, IGF binding protein [IGRBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligomorphic or other disorders. The present sequence is an oligomorphic and parts of the present invention (see AAF45151 and AAF45153-F4511). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serbornhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hopping such as neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood

The present invention relates to a method for ameliorating the effects of akin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF45151 and AAF45153-P45161). The method is useful for ameliorating the effects of psoriasis, inchyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, neoplasias scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperpoliferation of the inside of blood

The method comprises contacting the skin with an antisense oligomucleotide, (for Insulin-like Growth Factor [IGF] receptor, IGF binding protein [IGFBP] - or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligomucleotide which can be used to design the antisense oligomucleotides of the present invention (see AAF4151 and AF45153 - P45161). The method is useful for ameliorating the effects of psoriasis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a neoplasias, scleroderma, warts, benign growths, cancers of the skin, a brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood
                                                                                                                                                                                                                                                                                                                                                              Antisense therapy, antiproliferative, antinflammatory, antipsoriatic, cytostatic, dermatological, cardiant, virucide, ophthalmological, keloid, skin disorder, Insulin-like Growth Factor I receptor; IGF-1; pityriasis, IGF binding procein, IGFBP-2; IGFBP3; inflammation, psoriasis, pilatis, growth factor mediated cell proliferation, ichthyosis, serborrhoea; ruba, keratosis, neoplasia, scleroderma, wart, skin cancer; sclerotic disease, hypermeovascular condition, hyperplasis, kidney disease; neoblation of the retna, ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antibarane oligomolecuted, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP], which is capable of inhibiting or reducing growth factor mediated cell proliferation, inhibiting or reducing growth factor mediated cell proliferation, configuration or the present sequence is an oligomolecuted which can be used to design the antisense oligomolecutes of the present invention (see AAF45151 and AAF45153-CF 45161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serbornhoea, keloids, keratosis, cohthyosis, soleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic condition where the property of the inside of blood

IGF-I oligonucleotide #75

```
Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       The present invention relates to a method for ameliorating the effects of akin disorders. The method comprises contacting the skin with an antisense oligonuclectide, (for Insulin-like Growth Factor [IGF]) receptor, IGF binding protein [IGFBP] - 2 r IGFBP], which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotides of the present invention (see AAF4151 and AAF45153-F45161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pliaris, serborrhoea, Keloids, Keratosis, ichthyosis, pityriasis, ruba, pliaris, serborrhoea, Keloids, Keratosis, hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, hyperproliferation of the inside of blood
                                                                                                                                                                                                                                                                                                                                                                        Antisense therapy, antiproliferative, antinflammatory, antipsoriatic, cytostatic, dermatological, cardiant, virucide, ophthalmological, keloid, skin disorder, Insulin-1ke Growth Factor I receptor; IGF-1; pityriasis, IGF binding procein, IGFBF-2; IGFBF3; inflammation, psoriasis; pilatis; growth factor mediated cell proliferation; ichthyosis; serborrhoea; ruba, keratosis; neoplasia; scleroderma, wart, skin cancer; sclerotic disease; hyperneovascular condition; hyperplasia, kidney disease; neoblasia, condition; hyperplasia, kidney disease;

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    The present invention relates to a method for ameliorating the effects of artisense and comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide of the present invention (see AAF45151 and AAF45153-P45161). The method is useful for ameliorating the effects of psoriasis, ichthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, brain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Ameliorating the effects of a disorder, e.g. psoriasis, by administering V (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation.
                                                                                                                                              cytostatic; dermatological; cardiant; virucide; ophthalmological; keloid; skin disorder; Insulin-like Growth Factor 1 receptor; IGF-1; pityriasis; IGF binding protein; IGFB-2; IGFB93; inflammation; postiasis; pityriasis; growth factor mediated cell prolliferation; ichthyosis; serborrhoea; ruba; keratosis; neoplasia; scleroderma; wart; skin cancer; sclerotic disease; hyperneovascular condition; hyperplasia; kidney disease;

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an anticontering in the present electron. (For Insulin-like Growth Factor [166]-1 receptor, IGF binding protein [1678]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, or inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the antisense oligonucleotide is useful for ameliorating the effects of psoriasis, rithyosis, pityriasis, ruba, planis, serborrhoea, keloids, keracosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, chain or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood cossels or any other hyperplasia
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Antisense therapy, antiproliferative, antiinflammatory; antipsoriatic; cytostatic; dermatological; cardiant; virucide; ophthalmological; keloid; skin disorder; Insulin-like Growth Factor I receptor; IGF-1; pityriasis; IGF binding protein; IGFBP-2; IGFBP3; inflammation; psoriasis; pilaris; growth factor mediated cell proliferation; ichthyosis; serborrhoea; ruba;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 g
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    EEEEEEEEEEEE
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [GGF]-1 receptor, IGF binding protein [IGFB]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, of indiamation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be useful for ameliorating the effects of psoriasis, selfs. The method is useful for ameliorating the effects of psoriasis, nothyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, neoplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, chramping or skin, growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood vessels or any other hyperplasia
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       ö

The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [IGF]-1 receptor, IGF binding protein [IGFBP]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the attisma AAF45153- F45161). The method is useful for ameliorating the effects of psoriasis, inchipyosis, pityriasis, ruba, plaris, serborrhoea, keloids keratosis, neoplasias, soleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, the brian growth factor-mediated malignancies, other sclerotic disease, kidney disease, hyperproliferation of the inside of blood vessels or any other hyperplasia
                                                                                                                                                                                                                                                                                                                                                                                                                                                               Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or inflammation.

IGF-I oligonucleotide #381.

30-MAR-2001 (first entry)

Antisense therapy, antiproliferative, antinflammatory, antipsoriatic, cytostatic, dermatological, cardiant, virucide, ophthalmological, keloid, skin disorder, Insulin-like Growth Factor I receptor; IGF-1; pityriasis, IGF binding protein, IGFBP-2, IGFBP3, inflammation, psoriasis; pilaris; growth factor mediated cell proliferation; ichthyosis; serborrhoea; ruba; keratosis; neoplasia; scleroderma; wart; skin cancer; sclerotic disease; hypermeovascular condition; hyperplasia; kidney disease; neovascular condition; freina; ss.

```
The present invention relates to a method for ameliorating the effects of skin disorders. The method comprises contacting the skin with an antisense oligonucleotide, (for Insulin-like Growth Factor [108]-1 receptor, IGF binding protein [108P]-2 or IGFBP3), which is capable of inhibiting or reducing growth factor mediated cell proliferation, of inflammation and/or other disorders. The present sequence is an oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the antisense oligonucleotide which can be used to design the attisense oligonucleotide is useful for ameliorating the effects of psoriasis, F45161). The method is useful for ameliorating the effects of psoriasis, chthyosis, pityriasis, ruba, pilaris, serborrhoea, keloids, keratosis, noplasias, scleroderma, warts, benign growths, cancers of the skin, a hyperneovascular condition such as a neovascular condition of the retina, disease, kidney disease, hyperproliferation of the inside of blood to sessels or any other hyperplasia
                                                                                                                                                                                                                                                                                                                               Ameliorating the effects of a disorder, e.g. psoriasis, by administering UV (ultra-violet) treatment (optional) and an antisense nucleic acid that inhibits or reduces growth factor mediated cell proliferation and/or
